

OPDP v1.5: same average, different problems

The catalog expanded sharply, but the additions come through a much narrower source pipeline.

The catalog grew by 62%

3,359 AIM problems now make up 38.2% of the current OPDP.

OPDP v1.5 | previous n=5,426 | AIM additions n=3,359

Fewer sources, more uniform metadata

The additions come from one top-level source collection; the previous catalog spans 12.

Top-level source collection count; AIM additions contain 162 workshop-list subgroups

WHY IT MATTERS

The core contrast: 62% more records, 12 previous source collections versus one AIM collection with 162 workshop lists.

Difficulty changed shape, not level

The AIM batch is centered near the same D score, with fewer low and fewer frontier-tail problems.

Same center, tighter difficulty band

Mean intrinsic difficulty barely moved, but the AIM additions are much more concentrated.

Intrinsic difficulty D, 0-10 | row-level distribution comparison

Why D stayed flat: the factors canceled

Clearer routes offset deeper technical preparation and stronger known barriers.

Factor deltas are on 0-4 scales; contribution applies the published D weights

WHY IT MATTERS

Use the factor profile: clearer routes do not mean low preparation or low technical depth.

The new batch is more homogeneous - and differently labeled

T3 dominates, while partial and solved statuses replace the old catalog's mostly-open mix.

The additions cluster in T3

The new mean is slightly higher, yet the frontier tail is much smaller.

PREVIOUS

AIM ADDITIONS

T3: 86.8% -> 95.6%

T4+T5: 11.7% -> 4.0%

Tier shift chi-square p = 4.6e-39 | effect size Cramer V = 0.144

The status pipeline changed completely

This is the biggest reason raw tractability should not be read as full-solution ease.

PREVIOUS

AIM ADDITIONS

95.0% open -> 79.3% partial + 15.0% solved

Catalog status association p < 1e-300 | Cramer V = 0.890

WHY IT MATTERS

Status composition is the strongest cohort difference and affects downstream tractability.

What changes for someone choosing a problem

Expect more prerequisite breadth and formalization work, but somewhat clearer statements.

For solvers: more setup, clearer statements

Mean shift from previous to AIM additions on the published OPDP axes.

Positive is more burdensome except L, where higher would be more favorable | B is 0-5; others 0-10

The +1.0 tractability jump is mostly mechanical

T predicts checked partial progress in 100 combined hours, not complete solution.

Pre-round contribution sum +0.991; observed rounded mean shift +1.004

WHY IT MATTERS

Treat the +1.0 tractability shift as a partial-progress workflow signal, not full-solution ease.

AI and attention signals moved toward metadata defaults

AI classifications compressed toward neutral; human and context axes mostly reflect the new ingestion format.

AI difficulty moved toward the middle

Fewer additions are AI-favored or AI-hostile; nearly three quarters are neutral/mixed.

PREVIOUS

AIM ADDITIONS

MEAN AI DIFFICULTY

5.544 -> 5.638

AI DIFFICULTY SPREAD

SD 1.345 -> 1.021

AI-fit association $p = 1.25e-50$ | Cramer $V = 0.162$ | no empirical per-problem episodes

Attention signals mostly reflect metadata

The typical AIM problem is H2, but the previous catalog owns the long human-effort tail.

HUMAN EFFORT BANDS

CONTEXT SIGNALS

H is an order-of-magnitude prior; X and literature load are not direct measures of mathematical hardness

WHY IT MATTERS

Best practice: inspect D factors, V, F, P, B, status, confidence, and rationales together before choosing a target.
